

Card 29 attracts the most traffic but monetises materially worse than the panel

High customer appeal combined with weak downstream economics makes Card 29 the clearest intervention candidate.

CARD 29 CLICKS

PANEL RPC

£11.32

Panel benchmark

Same-application evidence

2.38× Card 30 click rate | **4.81×** Card 31 click rate

Card 29 also has the lower APR in 100% of these co-offers.

Interpretation

Card 29 is attractive to customers but weak downstream — creating a plausible diversion risk.

Diagnosis: intervene on Card 29 first, but removal needs a counterfactual test.

Removing Card 29 could improve revenue, but the result is highly sensitive to customer redistribution

Observed data identify the problem card; the unobserved post-removal customer response determines whether removing it creates value.

Upper-bound replacement case

All 315 Card 29 clickers with an alternative are assumed to transfer to the strongest remaining offer.

+£1,408 revenue

Empirically anchored case

For the 248 clickers who also saw Cards 30 + 31, redistribution uses observed behaviour from comparable applications where Card 29 was absent. The remaining 67 eligible clickers are stress-tested from 0–100% transfer.

At 100% remaining-group transfer: +£161

80.8% remaining-group transfer required for revenue break-even

The removal case is therefore not robust enough to justify a permanent change from observational data alone.

Recommendation: controlled Card 29 removal / deprioritisation test

Primary KPI: revenue / application

Secondary: sales / app • clickout • conversion • redistribution

Scenario outputs are modelled counterfactuals, not causal estimates.
